ALL INFO AT DOWNSAMPLED

equivalent amplitude can be computed using appropriate formulas. The maximum of the mean diurnal activity on disturbed days in summer occurs between the 63rd and 65th and near the 78th parallels. During winter and the equinoxes the maximum appears in the lower latitudes. No maximum appears at the 78th parallel. This distribution holds for the local-time component. The distribution of the maxima is shown in Fig. 1. On disturbed days the maximum activity in the first zone occurs at every hour of the day and night regardless of the season. In the second zone a sharp maximum appears in summer during daylight hours and a weak one in winter and the equinoxes. Both zones are divided by a wide zone of low activity. On quiet days in summer, the maximum activity is predominant in the second zone. Activity zones can be characterized in two ways: maxima distributed by latitude and by the diurnal rate of activity. The first results in annular zones and the second in spirals. Orig. art. has: 4 figures, 1 table, and 5 formulas.

TITLE: On the distribution of geomagnetic disturbances in space and time

SOURCE: AN SSSR. Mezhdunarodnyy geofizicheskiy komitet. III razdel programmy MOG (Geomagnetism i zemnye toki). Sbornik statey, no. 8, 1966. Geomagnitnyye issledovaniya (Geomagnetic research), 102-104

TOPIC TAGS: magnetic activity, universal time, geomagnetic latitude, local time component, ~~magnetic equator-auroral zone~~, ionospheric conductivity, geomagnetic disturbance

ABSTRACT: Magnetic activity R at a moment t in universal time is a function of two arguments: the geomagnetic latitude and the time. It can be expressed in the form $R = R(\varphi, t)$. The partial derivative $\partial R / \partial t$ determines the distribution of maxima of the local time component of the diurnal rate of magnetic activity. Maxima of the first harmonic of this function represent geometric places of points arranged in spirals. The addition of the second, third, and higher harmonics

Card 1/3

ACC NR. AT6034615

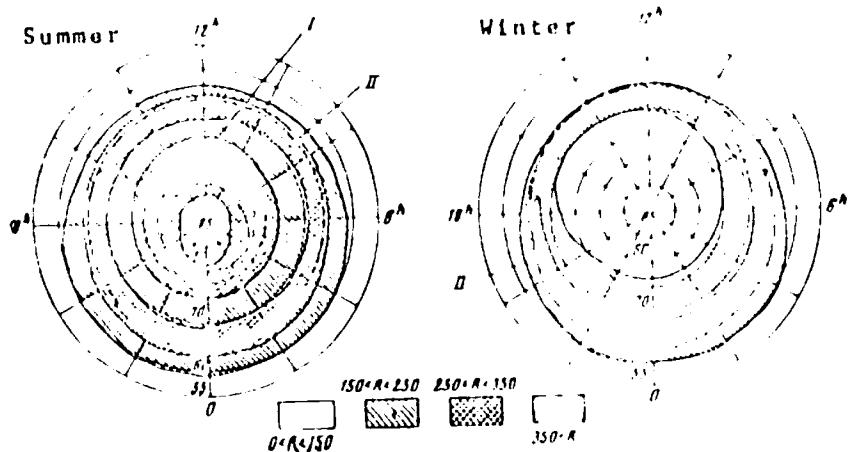

Fig. 1. Belts of equal magnetic disturbances.

yields a set of spirals. The partial derivative $\partial R / \partial \phi = 0$ determines the distribution of maxima of magnetic activity concerned with the geomagnetic latitude. Fig. 1 shows this distribution in belts depending upon the intensity of magnetic activity. There are three zones of magnetic activity. Zone I lies near the 78th parallel of geomagnetic latitude; zone II is near the 66th parallel; and zone III lies near

Card 2/3

ACC NR: AT6034615

the magnetic equator (not shown in Fig. 1.). In zones I and III the wave of diurnal variations with a noon maximum is predominant. There are two systems of disturbed magnetic currents with maxima in the auroral and equatorial zones which are near zones II and III. Zones of maximum conductivity in the ionosphere coincide with zones I and II. The maximum conductivity in zone II is on the midnight side and in zone I on the daytime side. Orig. art. has: 2 figures and 2 formulas.

TITLE: Selection of a spectrum of Legendre polynomials approximating an observed S_q-field

SOURCE: AN SSSR. Mezhdunodomstvennyy geofizicheskiy komitet. III razdel programmy MOG (Geomagnetizm i zemnyye toki). Sbornik statey, no. 8, 1966. Geomagnitnyye issledovaniya (Geomagnetic research), 23-30

TOPIC TAGS: orthogonal function, conditional equation, function spectrum, approximate function, geomagnetic field, spheric harmonic, Legendre polynomial

ABSTRACT: A function valid for an interval of values [a, b] can be expressed by the formula

$$Y(x) = \sum_{k=1}^{\infty} d_k O_k(x),$$

where $O_k(x)$ is an orthogonal function of the form

Card 1/3

ACC NR: AT6034608

$$\int_a^b G_m(x) \cdot G_k(x) dx = 0$$

when $m \neq k$. This function is given as the result of measurements obtained in a station network consisting of irregularly spaced N stations. The problem of measured results can be solved by the method of least squares if the quadratic difference of the function given and the measured results have a minimum in the system of conditional equations. Coefficients d_k obtained solving the system of equations contain errors which depend upon the spectrum of $G_k(x)$ functions. When the $G_k(x)$ functions in the system are not orthogonal, they can be transformed into orthogonal by auxiliary functions in which the coefficients d_k are substituted for a_k . The accuracy of the coefficient a_k is analyzed for the whole station network and a part of the R stations. The optimal spectrum of approximate functions is obtained when the ratio $|a_k/a_k| < 1$. This condition of approximate functions is applied for determining the approximate geomagnetic field during a quiet sun. Results of measurements of components of the geomagnetic field potential are expressed by sums of spherical harmonics completed with Legendre polynomials. The system of these equations is transformed into a system containing coefficients and

Card 2/3

ACC NR: AT6034608

other orthogonal functions. Analysis of the new system showed that the error of coefficients a_k increases with the increase of the number of stations, and the ratio $\Delta a_k/a_k$ becomes constant after k continues to grow. Orig. art. has: 1 table, 1 figure, and 36 formulas.

TITLE: Diurnal rate of magnetic activity during the IOY

SOURCE: AN SSSR. Mezhdunodomstvennyy geofizicheskiy komitet. III razdel programmy MOG (Geomagnetizm i zemnyye toki). Sbornik statey, no. 8, 1966. Geomagnitnyye issledovaniya (Geomagnetic research), 63-81

TOPIC TAGS: magnetic activity, geomagnetic index, current system, magnetic field, solar zenithal distance, universal time ~~espansione~~, local time component, auroral zone, ~~GEOMAGNETISM~~, geomagnetic disturbance

ABSTRACT: The diurnal rate of geomagnetic activity on perturbed days in 1957—1959 is studied using geomagnetic indices K of 92 observatories which followed the program of the IOY. The study is limited to the diurnal wave of geomagnetic variations and related to local time and universal time. Analysis of the diurnal wave of magnetic variations yielded the following results: 1) The first harmonic of the diurnal wave of equivalent amplitudes of magnetic activity on perturbed

Card 1/3

ACC NR: AT6034611

days is of the fundamental value. 2) Diurnal variations of magnetic activity can be related to both local and universal time. The component of universal time plays an important role in geomagnetic activity of perturbed days at all latitudes. 3) Variations of the component of local time by latitude and season can be represented as a superposition of two waves with maxima at noon and midnight. Phases of these waves do not change with latitude. These waves are analogous to the current system of a disturbed magnetic field. The error amplitude of the local time component attains a maximum at two geomagnetic zones: $\phi = 63^\circ - 67^\circ$ and $\phi \approx 78^\circ$. 4) The superposed waves are physically different. The level of disturbances is proportional to the square root of the cosine of the zenithal distance of the sun. The wave with a maximum at noon is predominant in equatorial and polar regions, and the wave with a maximum at midnight is predominant in the zone $\phi = 63^\circ - 67^\circ$. 5) The component of the universal time of variations consists of two parts, the symmetric and asymmetric, which differ from each other physically. The asymmetric part of the universal time component changes in phase by π in the transition from winter to summer of all latitudes. The error amplitude of the asymmetric part changes with latitude. The amplitude is near zero at middle latitudes and increases toward the auroral zone, being maximum at $\phi = 78^\circ$. The phase of the symmetric part of the universal time component is constant during the year, and the error

Card 2/3

ACC NR: AT6034611

amplitude of this part varies with the latitude like the change of the current system of the disturbed field. 6) The asymmetric part of the universal time component characterizes the magnetic activity during the rotation of the geomagnetic dipole and the distribution of the ionospheric conductivity. The symmetric part characterizes the dependence of the current system upon the eccentric rotation of the dipole. The authors thank V. S. Chesnokova for her help. Orig. art. has: 2 tables, 9 figures, and 32 formulas.

TITLE: Relationship between the electron concentration at altitudes
of 100 and 110 km and disturbances in the Earth's magnetic field

SOURCE: Geomagnetizm i aeronomiya, v. 6, no. 6, 1966, 1114-1116

TOPIC TAGS: ionosphere, ionospheric electron density, ~~Earth's magnetic~~
~~field~~

ABSTRACT: The effect of magnetic activity on electron concentration n_e at altitudes
of 100 and 110 km in the lower region of the E layer was investigated.
Values of n_e were taken during 36 rocket-borne experiments conducted in the
period 1947—1963 at middle latitudes. The degree of disturbance of the
Earth's magnetic field was estimated from 3-hour values of K-indices. It
was found that the electron concentration at midlatitudes increased as

Card 1/2

UDC: 550.388.2:550.385

ACC NR: AP7002202

magnetic activity increased (i.e., for K = 3—5 the electron concentration increased not less than 1.5 times at 110 km, and not less than 2 times at 100 km. It is postulated that for K73 corpuscular streams have an appreciable effect on electron concentration in the lower regions of the ionospheric E layer at midlatitudes.

Temperature coefficient of adsorption from solutions

I. V. P. Mishin and A. N. Karpov. *Colloid J.* 11, 8
S. R. 12, 302 (1930). Adsorption isotherms are given for Ca-glycerophosphate (I) at 0°, 20°, 50° and 75° and for
Ca-butyrate (II) at 0-50° and 75° on birch charcoal activated by heating in dil. HCl for 5 days, and heating at
100°. Thus a pos and II a neg temp. coeff as shown by
the table. For I the adsorption ratios are about 1.12

	Ca-glycerophosphate	Ca-butyrate
0°	7.50	11.75
20°	2.49	1.10
50°	1.07	1.70
75°	1.52	1.17
	4.00	4.15

1.35-1.5 and for II 1.0-0.9. II. V. P. Mishin and E.
I. Polozhanskaya. *Ibid.* 31, 22. Dipropanoic ester
was obtained by heating 11 g. Na in alk with 40.5 g.
malonic ester and then with 113 g. Ph or 81.7 g. PhBr
2 hrs. was used for each. Alk was boiled off and the aqu.
soln. exctd. with ether, dried and distd. giving 21 g. of
ether b. 248-50°. Dipropanoic acid was obtained by
hydrolysis of 21 g. of the ester by 27 g. KOH in 340 g. alk
heated for 3 hrs. The aqu. soln. was acidified, exctd. with
ether and crystd. from CHCl₃. Dipropanoic acid was
obtained from the malonic acid by heating at 160-200°

The yield of Ca salt obtained was 9.5 g. The adsorption
isotherms of Ca-dipropanoate were measured at
20, 50, 80 and 100° on birch charcoal by determ of the salt left
in soln. The ratios of the adsorptions for all concns. at
these temps. are about 1.12-1.14.

Differential thermograms of silk fibroin. V. P. Mishin
and A. I. Garbusov (1st Moscow Med. Inst.). "Bioskayka"
19, 605-0 (1954).—The differential thermograms of silk
fibroin and of natural silk exhibit two endothermic peaks,
one of which is of a lower temp., is reversible, and is associated
with the loss of sorption H₂O by the fibers; the other is of
a high temp., is not reversible, and results from the loss of
the fibroin cryst. structure. The thermographic method
can be applied in the identification of fibers of the mul-
berry and oak silkworms. A lower temp. limit has been
established for drying threads of fibroin or strands of silk
in the detn. of hygroscopic moisture. B. S. Levina

Title : Temperature Influence on Magnitude and Speed of Agar Swelling.

Orig Pub: Kolloidn. zh., 1957, 19, No 4, 472-477.

Abstract: The dependence of the magnitude and speed of agar swelling (S) in water and solutions of salts of the lyotropic series on the temperature T was studied using an automatically recording instrument. If the S process was not complicated with dissolution, the magnitude of S rises with T ; in the opposite case, the polytherm $\Delta V_\alpha = f(T)$ passes through a maximum, which is shifting to the side of lower T at a transition to media, in which the temperature factor of solubility of the swelling substance increases progressively. The speed of S

Kachestvennyy khimicheskiy polimikroanaliz (Chemical Qualitative Semimicroanalysis)
Moscow, Medgiz, 1960. 230 p. 20,000 copies printed.

Ed.: M.N. Kuvshinskiy; Tech. Ed.: N.K. Zuyeva.

PURPOSE: This book is intended for students of chemical analysis at medical schools
and institutes for stomatology.

COVERAGE: The textbook, which reflects the academic program in qualitative semi-microanalysis outlined by the General Chemistry Department of the First Moscow Order of Lenin Medical Institute imeni I.M. Sechenov, covers the theory of qualitative semimicro determination of the chemical elements or compounds constituting a substance or mixture of substances. Both chemical and physicochemical methods are discussed. The first is based on "analytical reactions" (characteristic reactions) of certain reagents while the second is based on the physical characteristics of the determined substance, e.g., absorption spectra, shape and color of crystals, the nature of luminescence under ultraviolet light, melting point, capacity for adsorption on various adsorbents, etc. The textbook also reviews chemical methods of analyzing inorganic substances. The authors thank Professor Ya.S. Przheborovskiy and N.D. Verdierevskaya for assistance.

ABSTRACT: Investigations of the solubility of cesium in a nitric acid solution by means of radiometric methods were carried out by the application of radioactive cesium Cs^{134} . Determination of solubility was carried out at $25 \pm 0.05^\circ\text{C}$ in the course of 3.5-4 hours. In a concentrated nitric acid solution ($d_4^{15} = 1.43-1.50$) the acid salt $\text{CsNO}_3\text{-HNO}_3$ with a composition of $\text{CsNO}_3\text{-HNO}_3$ is formed. The stability of this acid salt is between 0 and 50°C . With an increase of temperature the quantity of this salt decreases. From a 96% nitric acid solution the compound $\text{CsNO}_3\text{-HNO}_3$ is formed at low temperatures. There are 2 figures, 3 tables, and 7 references, 2 of which are Soviet.

TITLE:

The Production of the Isotope As⁷⁴ by Means of a Cyclotron
(Polucheniye izotopa As⁷⁴ na tsiklotrone)

PERIODICAL:

Atomnaya energiya, 1958, Vol 5, Nr 6, pp 560 - 561 (USSR)

ABSTRACT:

As⁷⁴ was obtained by the irradiation of metallic germanium with the external 10.8 MeV deuteron beam of the cyclotron (Ref 5).

The characteristic feature of the target was the fact that the cooling water immediately reached the inner surface of the irradiated germanium plate. The germanium plate was cast in a vacuum and was then ground to the dimensions 170.40.4 mm

The deuteron beam (60-70 μ A) is limited by a shutter so that

only a surface of 150.25 mm² of the germanium was irradiated.

The water consumption was 5 l/m.

Chemical separation was carried out as follows: After the irradiated sample had been boiled twice (for 15 to 20 minutes) in aqua regia, about 97-98 % of the activity had dissolved.

Card 1/3

The Production of the Isotope As⁷⁴ by Means of
a Cyclotron

SCV 89-5-5-1

The solution was steamed-in and extracted with 11 n HCl (method according to reference 6). The arsenic carrier used weighed 50 µg. Concentration of the arsenic isotope was carried out by the Marsh method (arsenic hydride). The two preparations, which were enclosed in an ampoule of 0.6 cm³, had an initial activity of 60 mC. The As⁷⁴ activity was measured by comparison with a Co⁶⁰ source by means of the micro- roentgenometer of the type "Kaktus" 30 days after irradiation. The total yield obtained by the formation of As⁷⁴ was: 25 µC/mA.h. ± 5 %. The half time was: T_{1/2} = 18.4 ± 0.4 d.

Professor B. S. Dzhelepov, I. P. Selinov, and Ye. Ye. Baroni interested themselves in this work. M. Z. Maksimov calculated the yield curve. Yu. A. Bliodze and I. I. Zhivotovskiy assisted in carrying out experiments. There are 2 figures and 10 references, 3 of which are Soviet.

TITLE:

⁷⁴
 β^+ -Izлучение As

PHYSICAL:

Radiation From As⁷⁴ Izluchenie As
Inventivna Akademii Nauk SSSR, Seriya Fizicheskaya
Vol. 1, No. 1, p. 631-638 (USSR)

ABSTRACT:

In December 1972 the authors obtained a radioactive isotope of As⁷⁴ (β^+ -ray) with a good specific activity. The characteristic features of this decay were examined and the physical nature of first the production of the preparation was discussed. This As⁷⁴ was produced by a bombardment of germanium with deuterium at an energy of 10.0 MeV. The results of the investigation of the β^+ - and γ -spectra are given. It is shown that the ground state of As⁷⁴ is of an E^0 -type. It is shown that the "fission" γ -ray spectrum has captured the after the "fission" γ -ray spectrum of both the β^+ -ray and the γ -ray. After the β^+ -ray spectrum the β^+ -ray spectrum has captured the γ -ray. In the back-ground of the β^+ -ray spectrum the γ -ray transitions of the transitions of the $K\alpha$ and $K\beta$ ionization-lines of the transitions of the $K\alpha$ and $K\beta$ ionization-lines, without back-ground, are clearly marked. The $K\alpha$ γ -radiation, without back-ground, is clearly marked.

Card 1/4

a transition of the type $2^+ \rightarrow 0^+$. With the $h\nu = 586$ keV transition, which connects it with the positron annihilation, transitions are more complicated, as the proportion of the K-transitions must be known in order to be able to determine α_K . Two methods in the determination of α_K are given. The spectrum of the γ -radiation of As^{74} was investigated by means of the recoil electrons. The relative intensity of three γ -lines was investigated with an equipment of a better resolution, and with the help of an equipment of a lower resolution, but of a previous intensity amplified by the hundredfold. It was attempted to find harder γ -lines in the radiation of As^{74} . The decay energy in the transmutation from $As^{74} \rightarrow Ge^{74}$ gives rise to the assumption that the levels of Ge^{74} are excited up to those of 2500 keV. Actually in the spectral range of 1200 keV a pronounced superelevation of the counting rate above the quiet background connected with the softer lines was observed. The intensity of this line is smaller by a factor of 42 than that of the annihilation line. It is assumed that in Ge^{74} the second level of excitation probably has an energy of 1200 keV. If this is true, it should be expected that a transition from the second level to the first level.

Card 2/4

Publication from As⁷⁴

307-4

about 100 keV exists and that this level forms a plateau with the 170 keV line. The ramifications in the decay scheme of As⁷⁴ are investigated. In the last chapter some remarks concerning the individual levels are given. As regards the conversion of the transition at $\Delta E = 166.3$ keV of Ge⁷⁴ it is shown that in this transition the ratio is $K\beta = 1.1 \pm 0.1$. In the investigation of the ratio K/B in the As⁷⁴ levels to the level at 166.3 keV of Ge⁷⁴ it is shown that the ratio K/B for this transition is normal. The level at 1100 keV of Ge⁷⁴ is probably a second vibration level with the characteristic 2. The second excited level of Ge⁷⁴ is probably near 1500 keV and is of the type 2'.

TITLE: Solubility in the system $\text{CsNO}_3 - \text{HNO}_3 - \text{H}_2\text{O}$ at temperatures of 0, 35, and 50°C

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 8, no. 1, 1963, 226 - 230

TEXT: Mixtures of $\text{CsNO}_3 - \text{HNO}_3 - \text{H}_2\text{O}$ were prepared in different concentrations at 0, 35, and 50°C and analyzed according to Schreinemakers. Analogous studies were carried out at 25°C to define previous data more exactly. The results were used to plot the solubility isotherms (Fig. 1). In view of the cesium ion being able to reduce HNO_3 dissociation, and of HNO_3 tending towards polymerization, the formula $\text{Cs}[\text{HNO}_3 \cdot \text{NO}_3]$ is suggested for the solvate $\text{CsNO}_3 \cdot \text{HNO}_3$, and $\text{Cs}[(\text{HNO}_3)_2 \cdot \text{NO}_3]$ for $\text{CsNO}_3 \cdot 2\text{HNO}_3$. The formation of complexes having the form $\text{M}[\text{HNO}_3 \cdot \text{NO}_3]$ and $\text{M}[(\text{HNO}_3)_2 \cdot \text{NO}_3]$ is discussed. There are 2 figures and 1 table.

TITLE: A study of heterogeneous equilibria in the ternary system uranyl nitrate - nitric acid - water. Part I. Solubility isotherms of the system uranyl nitrate - nitric acid - water at 25, 35 and 50C

SOURCE: Radiokhimiya, v. 6, no. 4, 1964, 454-459

TOPIC TAGS: heterogeneous equilibrium, solubility isotherm, uranyl nitrate, nitric acid solution, uranyl nitrate disolvate

ABSTRACT: The isothermal method was used to study the solubility of uranyl nitrate in nitric acid solutions at 25, 35 and 50C. In this study, uranyl nitrate was determined gravimetrically in the usual way (precipitation of ammonium diuranate which yields uranium oxides on heating), nitric acid was determined by titration with NaOH after binding the U with ammonium oxalate, and water was determined by difference. The solubility isotherms constructed for these 3 temperatures (see Fig. 1 of the Enclosure) consist of 4 branches, corresponding to the solubility of

TITLE: Synthesis of phthalocyanines of certain heavy metals

SOURCE: Zhurnal obshchey khimii, v. 37, no. 1, 1967, 280

TOPIC TAGS: uranium compound, thorium compound, hafnium compound, antimony compound, bismuth compound, phthalocyanine

ABSTRACT: Phthalocyanines of uranium, thorium, hafnium, antimony and bismuth were synthesized from o-phthalonitrile and acetates of UO_2^{2+} , Th^{4+} , Hf^{4+} , Sb^{3+} and Bi^{3+} at 250-300°. The absorption spectra of the products of the synthesis reaction showed several bands at 640-799 m μ , which indicate the formation of various forms of phthalocyanines. For instance, three absorption bands with peaks at 644, 659 and 694 m μ were found in a benzene solution of the product of the synthesis of uranium phthalocyanine. Chromatography on Al_2O_3 was used to separate a form of uranium phthalocyanine characterized by a single strong absorption band in benzene at 644 m μ . From a benzene solution of the raw reaction product resulting from the reaction of synthesis of uranium phthalocyanine, ethyl ether "salted out" a compound having a band with a peak at 693 m μ . In the remaining solution, a single absorption band with

Card 1/2

UDC: 547.584

ACC NR: AP7006252

a peak at 643 m μ was observed. The absorption peaks for the reaction products of phthalocyanines are as follows: 646 and 695 m μ for thorium, 632, 665 and 698 m μ for hafnium, 642, 659 and 706 m μ for bismuth, and 670 and 690 m μ for antimony. The spectra of thorium and hafnium were taken in benzene, and those of antimony and bismuth in dimethylformamide. The observed variety of the forms of heavy metal phthalocyanines is apparently due to the formation of complexes with more or less intricate structures, as well as to the variable valence of the complex-forming reactants.

TITLE: Heat Treatment of Upsetting Tools Made of 12D (Kh12P) Steel
PERIODICAL: Tr. Kazansk. aviat. in-ta, 1958, Vol. 33-34, pp. 375-382

TEXT The authors developed heat-treatment conditions for the 10.12P steel of the following composition (in%): C=1.5, Cr=11, V=0.71, Mn=0.33, Si=0.24, and P=0.02, ensuring a higher resilience. Hardening was effected at temperatures between 950 and 1,050°C with air and oil-cooling, single and triple tempering at 500°C for one hour, as well as isothermal hardening at 1,050°C with cooling in salpeter at 300°C and subsequent cooling in the furnace. The results of heat treatment were rated by the magnitude of absorbed work (A) and the torsion angle (ϕ) during impact torsion. The following values were obtained for the specimens after hardening at 950-970°C with cooling in the air and tempering at 500°C: A = 12.94 kgm and $\phi = 41.25^\circ$. The highest values of absorbed work during impact torsion were obtained for the specimens after hardening at 1,050°C with cooling in the air and tempering at 500°C.

torsion are obtained with oil hardening at 1,150°C and triple tempering at 500°C, i.e. $A = 26.9 \text{ kgm}$ and $\psi = 190^\circ$. The authors recommend the following heat-treatment conditions for impact tools made of Kh12P steel: hardening heating up to 1,150° during 1.5-2 hours (depending on the tool size), cooling in oil and triple tempering for one hour per operation at 500°C. Such a treatment ensures a hardness of $R_C 54\text{-}59$ on the operating surface on the impact tool. There are 6 figures and 2 references.

Comparative Investigations of Steels for Bolts of Hot Connections
Aircraft

PERIODICAL: Tr. Kazansk. aviat. in-ta, 1968, Vol. 41, pp. 55-60

TEXT Physicomechanical comparative investigations were carried out on three brands of steel 30KhGSA (30KhGSA), 18H15 (Kh18N1B) and 18KhBA (18KhNVA). The effect of repeated heating was determined at 500°C on α_K , as well as the effect of the test temperature (20-650°C) on δ_b , σ_y , ν_K , the linear expansion coefficient, and the strength of the bolts at expansion with skewing. It is recommended, on the basis of the data obtained, to use steel 18KhNVA for bolts operating at high temperatures.

TITLE: A New Microchemical Reaction for Copper Ions in the Range of 10⁻⁵ to 10⁻⁶ Molar Concentration with

PERIODICAL: Prakticheskaja mineralogija, No. 1, 1978, p. 11-12.

ABSTRACT: A new microchemical reaction for determining Cu²⁺ ions in H₃BO₃ solution was studied. It combines with Cu²⁺ ions in a 1:1 ratio in a Jhenfa "O" solution of I in an H₃BO₃ medium. Silicate gel is formed at a concentration containing $\leq 10^{-5}$; Cu/m, inhibitor in salt at supersaturation. When the concentration is greater (10⁻⁴-10⁻³ g/m), a dark blue, fine, crystalline precipitate comes down at once. The washing down of precipitate by water in acid solutions may be promoted by addition of sodium, fine-ground K₂O₂, or Na₂O₂. Pb, Ag, and Hg act as inhibitors. Centrifugation and ignition are used for Cu in ores, minerals, and minerals and non-metallic rocks. In order to determine Cu in steel, the Pb has to be bound by salt. The detection limit is 10⁻⁶ M, which can be detected if 10⁻⁵ g/m. 10 g tin are required to analyze 10 g Cu.

LL

Mišina, A. P. Some conditions for splitting of mixed
Abelian groups. Ukrains. Mat. Zurnal 3, 218-232 (1951).
[more]

(Russian)

[For reference, see Baer, Ann. of Math. (2) 37, 766-781 (1936).] Let A be a mixed abelian (additive) group with maximal periodic subgroup F ; let $\mathfrak{I}^* = A/F$; let F_2 be the primary component of F for the prime 2. The problem is to investigate what conditions will insure the converse of the result: if A splits (that is, if $A = F + \mathfrak{I}$, where $\mathfrak{I} \cong \mathfrak{I}^*$), then every pair of automorphisms, one of F and the other of \mathfrak{I}^* , is induced by a suitable automorphism of A . Denote by ψ_0 the automorphism of F which maps each element into its negative. The group A splits if and only if A has an automorphism ϕ which induces ψ_0 in F , which induces the identity map in \mathfrak{I}^* , and which furthermore satisfies the condition that for each $a \in A$, there exists $f \in F$ such that $\phi(a) = a + 2f$. The author studies various restrictions imposed on either F or \mathfrak{I}^* which yield assertion (E): if the pair of automorphisms, ψ_0 of F and the identity map of \mathfrak{I}^* , is induced by an automorphism of A , then A splits. For example, if $\mathfrak{I}^* = 2\mathfrak{I}^*$, then A satisfies assertion (E). If F_2 is zero, then A satisfies (E). Indeed, the general problem may be reduced to the case $F = F_2$. If \mathfrak{I}^* has finite rank and if $F = F_2$, then A satisfies (E). If $D(\mathfrak{I}^*)$ exists [cf. Baer's Definition 3; 2] and if $F = F_2$, then A satisfies (E). Other sufficient restrictions are also presented. R. A. Good.

TITLE: The use of gas chromatography in the production of monomers for synthetic
rubber

SOURCE: Vsesoyuznaya nauchno-tehnicheskaya konferentsiya po gazovoy khromatogra-
fii - 2d, Moscow, 1962. Gazovaya khromatografia (Gas chromatography), trudy

k. rentsi. Moscow, Izd-vo Nauka, 1964, 109-115

TOPIC TAGS: gas chromatography, monomer production, two-stage chromatography,
integral volume detector, katherometer, hexene demethylation, synthetic rubber,
isopentane dehydration, flame ionization detector, isoprene polymerization

ABSTRACT: This is a survey of applied and applicable methods for chromatographic
analysis. For example, two-stage chromatography for contact separation of the follow-
ing components is described: H₂, N₂ + O₂, CH₄, C₂H₆, C₃H₈, C₄H₁₀, C₄H₆ and C₄H₈.
Integral volume detectors with autorecorders are applicable where no very low concen-
trations are involved (e.g. the mixture from the catalytic dehydration of isopentane).

Chromatographic equipment with a batharometer is indicated for substances with a boiling point above 40-45°C. Those which dissolve easily in alkali or where low concentrations (less than 1%) have to be determined. This equipment is described and illustrated (chromatographic separation of complex mixtures from hexene demethylation, or of perylene in isoprene concentrate). The sensitivity threshold may be increased by using a thermo-chemical monitor (from the Kh-2M apparatus). Standard calibration with an artificial mixture is required for this equipment. The calibration coefficients were found to be constant for considerable variations of concentration and some modification of test conditions. This set-up was also used to determine admixtures of butylenes and methyl-ethyl ether in divinyl of high purity and those of n-butylene in iso-butylene. The sensitivity of gas chromatography may be increased by concentration of impurities to a degree where they can be detected, or by increasing the sensitivity of the detector. A flame-ionization detector has been used at the NIIMSK. This considerably facilitates control of product purity and makes possible determination of the basic polymerization centers; thus, e.g., cyclopentadiene was determined as one of the centers of catalytic isoprene polymerization, appearing as early as the dehydration stage. TITLE: A Variant of the Penfield Method for the Micro-determination of Water in Minerals (Variant metoda Penfil'da dlya mikro-opredeleniya vody v mineralakh)

PERIODICAL: Zavodskaya Laboratoriya, 1959, Vol 25, Nr 2, p 162 (USSR)

ABSTRACT: The Penfield determination method was varied a little as to render it applicable for microanalyses. Since a fast separation of bound water can only be achieved at high temperatures, glowing heat is produced by a gas-oxygen flame and quartz tubes in which a temperature of 1600° can be obtained within 2 or 3 minutes. The enlarged part of the Penfield tube is cooled by solid carbonic acid in order to achieve a complete water condensation. In the presence of fluorides or iron oxide minium is added to the weighed portion, thus freeing only 0.2% of 1.8 - 3.3% fluorine and water in the glowing of phlogopite. By this method water was determined in mica, amphiboles, zeolites, and water containing glasses; here, a microanalytical scales VM-20 was used. The results obtained correspond closely to Penfield and Hecht-Alimarin results

TITLE: The PT-projection of the Alumina-water System
(PT-proyektsiya sistemy kremnezem-voda)

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 3,
pp 645-646 (USSR)

ABSTRACT: The system mentioned in the title is a limiting system for many silicate systems with volatile components which are of importance in petrology and mineralogy. At least 5 phases exist in this binary system at high temperatures: cristobalite, tridymite, quartz, liquid and vapor. It is (according to Ref 1) a multiple system with one degree of freedom. In general, such system must have 5 invariant points and 10 monovariant lines. The present case is simplified by the circumstance that all crystalline phases are of the same chemical composition, and only two monovariant reactions (1)-(6) are possible between the phases. In the reactions (4)-(6) the liquid and gaseous phases do not take part, so that the equilibria are degenerated. This simplifies very much the building-up of a basic scheme for the system mentioned in

Card 1/3

The PT-projection of the Alumina-water System

SOV/20-126-2-50/6

the title (Fig 1). All 3-phase monovariant equilibria are stable in this scheme. This is in agreement with the experiment. In the present case, the degenerated equilibria are stable on both sides of the invariant points. The corresponding curves pass over into one another without changing their directions. The variant, in which the equilibrium tridymite + + gas = melt is unstable, is excluded from consideration. An experiment, however, makes it easily clear that tridymite can coexist with the melt. As the experimental PT-diagram of the mentioned system (Ref 2) is incomplete, and does not agree with the theoretical scheme (Fig 1), the authors achieved some precision and completion by their experiments. The resulting experimental PT-diagram corresponds to the theoretical scheme (Fig 1. Figure 2 shows this experimental diagram (Refs 3, 4). A comparison of this diagram with the material found by other investigators shows differences in the position of various points and lines. There are 2 figures and 4 references, 1 of which is Soviet.
